Fibrinolytic Bacterial Enzymes with Thrombolytic Activity

Fibrinolytic Bacterial Enzymes with Thrombolytic Activity Abstract This book describes the fibrinolytic enzymes of microbial origin that are able to dissolve endogenous thrombi in vivo. The fibrinolytic enzyme streptokinase for example, is produced by β -hemolytic streptococci and exerts its enzyme action indirectly by activating plasminogen. On the other hand, staphylokinase is

CV Pharmacology | Thrombolytic (Fibrinolytic) Drugs

Thrombolytic drugs dissolve blood clots by activating plasminogen, which forms a cleaved product called plasmin. Plasmin is a proteolytic enzyme that is capable of breaking cross-links between fibrin molecules, which provide the structural integrity of blood clots. Because of these actions, thrombolytic drugs are also called "plasminogen activators" and "fibrinolytic drugs."

The available thrombolytic agents such as urokinase are highly expensive, antigenic, quite unspecific, pyretogenic and hemorrhagic. Therefore, the production of fibrinolysing enzymes, which rapidly dissolve thrombi within the vascular tree, without the detriments by microorganisms, as described in this book, is the desirable aim of today's research.
