What is the formal definition of non-deterministic automata?

Intuitively, a non-deterministic automaton is an automaton in which there is no clearly defined path for each input.

There might be many paths, there might be none at all. Let me show you an example: There might be many paths, there might be none at all.

Unit 3 Regular Operations Deterministic and Nondeterministic Automata Reading: Sipser, chapter 1, 2. Reminder Regular Languages A regular language is a language for which there exists a recognizing finite automaton. Notes: 1. For every symbol a in the language L , $a = \{a\}$ is regular. 2. For every word $w = a_1 a_2 \dots a_n$ over the language L , $w = \{w\}$ is regular. Proof: Draw DFAs. 3. Regular

As there is a finite automaton for every regular expression we can generate a finite automaton for the regular grammar. Conversion of Regular Grammar into Finite Automata Given a regular grammar G , a finite automata accepting $L(G)$ can be obtained as follows: The number of states in the automata will be equal to the number of non-terminals plus one. Each state in automata represents each non

Universal Turing machine - Wikipedia

In computer science, a universal Turing machine (UTM) is a Turing machine that can simulate an arbitrary Turing machine on arbitrary input. The universal machine essentially achieves this by reading both the description of the machine to be simulated as well as the input thereof
